

Long URLs

Real-world URLs from Google search, S3 signed URLs, and JWT auth flows routinely run into the hundreds of characters. The interesting question is how the renderer handles a URL that is longer than the available line width — does it break the URL across a line, hyphenate it, run past the right margin, or wrap cleanly?

Sentence-length URLs

Visit https://en.wikipedia.org/wiki/Lorem_ipsum for background reading.

Compare with

https://en.wikipedia.org/wiki/An_Essay_Concerning_Human_Understanding which has a noticeably longer slug.

Paragraph-length URLs

A 200-character URL:

<https://example.com/api/v2/resources/very-long-endpoint-name-that-goes-on-and-on-and-on-and-ever>

A 500-character URL:

[illegible]

Bare URL forms

Bare URLs work too: <https://www.commonmark.org/help/> — and these may render the same as the angle-bracketed form, depending on whether autolinks are enabled.

A URL with parentheses and percent escapes inside the path:

<https://en.wikipedia.org/wiki/Markdown> (markup language) — and a query-string

version with percent-encoded spaces:

<https://example.com/search?q=lorem%20ipsum%20dolor>

URL preceded by a parenthesis

Like in academic citations: (see <https://example.com/long-paper-name>).

URL inside emphasis

Find more at <https://example.com/highlighted-link> in italic.

And **<https://example.com/bold-autolink>** in bold.
