

Mixed block transitions

Where one block type ends and another begins is a fertile place for parser bugs. This gallery walks every adjacent pair: paragraph-to-list, list-to-code, code-to-quote, quote-to-table, table-to-paragraph.

Paragraph to fenced code

A paragraph immediately before a fenced code block.

```
print("the line above ends with a sentence")
```

A paragraph immediately after.

Heading to code

Heading

```
Bare code block right after heading
```

List to code

- Item one
- Item two

```
print("a code block immediately after a list")
```

The code should NOT be absorbed into the second list item; it should be a separate block.

Code to list

```
print("end of code")
```

- Item one
- Item two

Quote to table

| A quote that ends here.

immediately	followed
by	a table

Table to quote

a	b
1	2

| A quote immediately after a table.

Paragraph to thematic break

A paragraph of content.

Another paragraph after the break.

Thematic break adjacent to heading

Heading right after a break

Body text.

Tight transitions

End of paragraph 1.

- list item starts right after a line of paragraph 1

The above might or might not work — strict CommonMark says it should; many parsers require a blank line. We render it as if there were a blank line if we detect a list marker at column zero.

Quote nested in list, code nested in quote

- Outer list item.
 - > Quote nested in the item. > > python > print("code nested in the quote in the list") > >> End of quote.

- Second outer item.
